SMMK modification

Chanwoo Lee, May 17, 2020

1 SMMK symmetric adjustment

The current SMM kernel treats X and X^T differently. To address this, we use

$$X^* = \begin{pmatrix} 0 & X^T \\ X & 0 \end{pmatrix} \quad \text{or} \quad \tilde{X}^* = \begin{pmatrix} 0 & X \\ X^T & 0 \end{pmatrix} \in \mathbb{R}^{(m+n)\times(m+n)},$$

as input data matrix. First, we show that the output boundary of the SMMK is invariant over whether we use X^* or $\tilde{X}^*$.

Theorem 1.1. *Suppose that for a given matrix kernel $\boldsymbol{K}$ there exists vector valued kernel K that satisfies (the sufficient condition for valid kernel)*

$$[\boldsymbol{K}(X, X')]_{i,j} = K(X_{\cdot i}, X'_{\cdot j}).$$

Also assume that the kernel K is symmetric in the sense that

$$K(\boldsymbol{a}, \boldsymbol{b}) = K(\pi(\boldsymbol{a}), \pi(\boldsymbol{b})),$$

where $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{R}^m$, and π is an arbitrary permutation function. Then SMMK functions from input X^* and $\tilde{X}^*$ have the same classification.

Proof. Let $\boldsymbol{h}$ be the corresponding feature map to the kernel $\boldsymbol{K}$ such that

$$\boldsymbol{K}(X, X') = \boldsymbol{h}(X)^T \boldsymbol{h}(X').$$

Consider the following SMMK primal problem.

$$(P) \qquad \min_{B,b,\boldsymbol{\xi}} \quad \frac{1}{2}\|B^*\|^2 + C\sum_{i=1}^{N}\xi_i \tag{1}$$
$$\text{subject to} \quad y_i(\langle B^*, \boldsymbol{h}(X_i^*)\rangle + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, N.$$

It is enough to show that there exists permutation function $\boldsymbol{\pi} : \mathbb{R}^{d\times(m+n)} \to \mathbb{R}^{d\times(m+n)}$ such that

$$\boldsymbol{\pi}(\boldsymbol{h}(X_i^*)) = \boldsymbol{h}(\tilde{X}_i^*) \text{ for all } i = 1, \ldots, N. \tag{2}$$

Because if (2) holds, then the equation (1) can be expressed as

$$(P) \qquad \min_{B,b,\boldsymbol{\xi}} \quad \frac{1}{2}\|\boldsymbol{\pi}(B^*)\|^2 + C\sum_{i=1}^{N}\xi_i$$
$$\text{subject to} \quad y_i(\langle \boldsymbol{\pi}(B^*), \boldsymbol{\pi}(\boldsymbol{h}(X_i^*))\rangle + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, N,$$

which is the primal problem from input $\tilde{X}^*$.

Notice that there exists vector valued feature mapping h such that

$$\boldsymbol{h}(X_i^*) = (h([X_i^*]_1), h([X_i^*]_2), \cdots, h([X_i^*]_{m+n})),$$

where $[\cdot]_i$ is the $i-$th column of the matrix. Let $\boldsymbol{\pi}_1$ be the column-wise permutation such that

$$\boldsymbol{\pi}_1(\boldsymbol{h}(X_i^*)) = ((h([X_i^*]_{n+1}), \cdots, h([X_i^*]_{n+m}), h([X_i^*]_1), \cdots, h([X_i^*]_n))$$

By the symmetricity of the vector valued kernel K, the corresponding feature map h has the property that

$$\{h(\boldsymbol{a})_i : i = 1, \ldots, d\} = \{h(\pi(\boldsymbol{a}))_i : i = 1, \ldots, d\},$$

for any $\boldsymbol{a} \in \mathbb{R}^{m+n}$ and permutation $\pi : \mathbb{R}^{m+n} \to \mathbb{R}^{m+n}$. To be specific, the permutation does not change components of the image of h. Therefore, there exist row-wise permutations $\pi_{2,j}$ such that

$$[\boldsymbol{\pi}_1(\boldsymbol{h}(X_i^*))]_j = \pi_{2,j}([\boldsymbol{h}(\tilde{X}_i^*)]_j).$$

By defining $\boldsymbol{\pi}_2 = (\pi_{2,1}, \cdots, \pi_{2,m+n})$, we have $\boldsymbol{\pi} = \boldsymbol{\pi}_2 \circ \boldsymbol{\pi}_1$ that satisfies (2). $\qquad \square$

In addition, we can show that SMMK with X^* has the same classifier with X in the linear case.

Theorem 1.2. *In the linear SMM case, the classifier $\boldsymbol{f}(X; \hat{B}) = \langle \hat{B}, X \rangle + \hat{b}$ form the cost C in the primal problem is the same as the classifier of $\boldsymbol{f}(X^*; \hat{B}^*) = \langle \hat{B}^*, X^* \rangle + \hat{b}$ with the half cost $\frac{1}{2}C$. To be specific, $\hat{B}^* = \begin{pmatrix} 0 & \hat{B}^T \\ \hat{B} & 0 \end{pmatrix}$*

Proof. The primal problem of linear SMM is

$$(P) \qquad \min_{B,b,\boldsymbol{\xi}} \quad \frac{1}{2}\|B^*\|^2 + C\sum_{i=1}^N \xi_i \qquad (3)$$
$$\text{subject to} \quad y_i(\langle B^*, X_i^* \rangle + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, N.$$

Consider the following equality

$$\langle B^*, X^* \rangle = \left\langle \begin{pmatrix} B_1 & B_2 \\ B_3 & B_4 \end{pmatrix}, \begin{pmatrix} 0 & X^T \\ X & 0 \end{pmatrix} \right\rangle$$
$$= \left\langle \begin{pmatrix} 0 & B_2 \\ B_3 & 0 \end{pmatrix}, \begin{pmatrix} 0 & X^T \\ X & 0 \end{pmatrix} \right\rangle$$
$$= \langle B_2^T + B_3, X \rangle$$
$$= \langle B, X \rangle \text{ where } B = B_2^T + B_3.$$

The second equality holds because $B_1 = B_4 = 0$. since B_1 and B_4 do not affect the constraint. Then, (3) becomes

$$(P) \qquad \min_{B,b,\boldsymbol{\xi}} \quad \frac{1}{4}\|B\|^2 + C\sum_{i=1}^N \xi_i \qquad (4)$$

2

$$\text{subject to} \quad y_i(\langle B, X_i \rangle + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, N.$$

In (4), we use the inequality that $\|B^*\|^2 = \|B_2\|^2 + \|B_3\|^2 \geq \frac{1}{2}\|B_2 + B_3\|^2 = \frac{1}{2}\|B\|^2$ where equality holds when $B_2 = B_3^T$. $\qquad\square$

In the nonlinear case, we can not guarantee that the output boundaries from X and X^* are the same. The following is simple illustration of different boundary in the vector case SMMK. We have training data $(X_1, y_1), \ldots, (X_{40}, y_{40})$ where $X_i \in \mathbb{R}^2$ and $y_i \in \{-1, +1\}$. I trained the data with input $X \in \mathbb{R}^{2\times 1}, X^T \in \mathbb{R}^{1\times 2}, X^* \in \mathbb{R}^{4\times 4}$ and $\tilde{X}^* \in \mathbb{R}^{4\times 4}$. Figure 1 shows the SMMK boundary with polynomial kernel on each input. We can notice that the case of X^* and $\tilde{X}^*$ have the same output, which is verified in Theorem 1.1. In addition, the symmetric adjustment boundary is in the middle between boundaries with X and X^T. This makes the boundary fluctuate less and stable. We can think symmetric adjustment as improvement from vector case kernel method which has steep fluctuation in subfigure A.
